Population Models

The state of the system is a population vector, \( n \), with one entry for each population variable, the entry recording the current value.
Population Models

The state of the system is a population vector, \( n \), with one entry for each population variable, the entry recording the current value.

Each event will update the vector according to the update vector as a single atomic step after an exponentially distributed delay.
Population Models

The state of the system is a population vector, $n$, with one entry for each population variable, the entry recording the current value.

Each event will update the vector according to the update vector as a single atomic step after an exponentially distributed delay.
Population Models

Each event will update the vector according to the update vector as a single atomic step after an exponentially distributed delay.

\[ n \rightarrow n + u \]
Continuous Approximation

A discrete interpretation (CTMC) is based on discrete events and integer values of variables.
Continuous Approximation

A discrete interpretation (CTMC) is based on discrete events and integer values of variables.

As the population $N$ increases the values and the frequency of events both increase.
Continuous Approximation

A discrete interpretation (CTMC) is based on discrete events and integer values of variables.

Continuous Approximation

A discrete interpretation (CTMC) is based on discrete events and integer values of variables.

As the population $N$ increases the values and the frequency of events both increase.

Using continuous state variables to approximate the discrete state space and ordinary differential equations to represent the evolution of those variables over time we can make an alternative continuous interpretation.

Fluid approximation of CTMC with deterministic delays

Jane Hillston.
Small Example

Consider a simple genetic network consisting of a single gene expressing a protein which acts as a self-repressor.

\[(G) \xrightarrow{\text{transcription}} M \xrightarrow{\text{translation}} P\]
Small Example

Consider a simple genetic network consisting of a single gene expressing a protein which acts as a self-repressor.

We explicitly model transcription (synthesis of mRNA from the gene), translation (synthesis of protein from mRNA), and degradation.
Small Example

Consider a simple genetic network consisting of a single gene expressing a protein which acts as a self-repressor.

We explicitly model transcription (synthesis of mRNA from the gene), translation (synthesis of protein from mRNA), and degradation.
Small Example

Two variables, $M$ and $P$, capture the amount of mRNA and protein (as molecule counts) respectively, modified by four transitions:

- $((1, 0), \alpha_M \frac{1}{1+(P/P_0)^h})$: transcription of mRNA.
- $((0, 1), \alpha_P M)$: translation of mRNA into protein $P$.
- $((-1, 0), \beta_M M)$: degradation of mRNA.
- $((0, -1), \beta_P P)$: degradation of the protein $P$.
Small Example

For this model we can derive a CTMC and the following system of ODEs:

\[
\frac{dm(t)}{dt} = \frac{\alpha_m}{1 + (p(t)/P_0)^h} m(t) - \beta_m m(t)
\]

\[
\frac{dp(t)}{dt} = \alpha_p m(t) - \beta_p p(t)
\]
Convergence of Models

Convergence of Models

Kurtz’s Theorem [1970]

As population $N$ grows large ($\infty$), the behaviour of the population and individual models become indistinguishable.
Example Revisited

A trajectory of the ODE model compared with trajectories of the CTMC for protein variable $P$, for increasing values of $N$. 

Jane Hillston.
Fluid approximation of CTMC with deterministic delays
Delayed Population Models

As previously the state of the system is a population vector, $n$, with one entry for each variable.
Delayed Population Models

As previously the state of the system is a population vector, \( n \), with one entry for each variable.

Some events will generate an update after the exponentially distributed occurrence of the event and another update after the deterministically timed delay.
Delayed Population Models

As previously the state of the system is a population vector, $n$, with one entry for each variable.

Some events will generate an update after the exponentially distributed occurrence of the event and another update after the deterministically timed delay.
Delayed Population Models

As previously the state of the system is a population vector, $n$, with one entry for each variable.

Some events will generate an update after the exponentially distributed occurrence of the event and another update after the deterministically timed delay.
Example as a delayed population model

In our model, we can easily introduce delays by replacing transcription and translation by delayed transitions:

- $((0, 0), \alpha_M \frac{1}{1+(P/P_0)^n}, (1, 0), \sigma_M)$: delayed transcription;
- $((0, 0), \alpha_P M, (0, 1), \sigma_P)$: delayed translation.

The degradation transitions remain the same.

Delayed CTMC

Jane Hillston.
Fluid approximation of CTMC with deterministic delays
Delay Differential Equations

Delay Differential Equations (DDE) are differential equations in which the derivative can depend also on past values of the function

\[
\frac{dx(t)}{dt} = F(t, x_t)
\]
Delay Differential Equations

**Delay Differential Equations (DDE)** are differential equations in which the derivative can depend also on past values of the function

\[
\frac{dx(t)}{dt} = F(t, x_t)
\]

The initial condition of a DDE is no longer a single point, but rather a function \( \varphi : [-d, 0] \rightarrow \mathbb{R}^n \).
Delay Differential Equations

Delay Differential Equations (DDE) are differential equations in which the derivative can depend also on past values of the function

\[ \frac{dx(t)}{dt} = F(t, x_t) \]

The initial condition of a DDE is no longer a single point, but rather a function \( \varphi : [-d, 0] \rightarrow \mathbb{R}^n \).

Our models give rise to DDEs with constant delays:

\[ \frac{dx(t)}{dt} = F(t, x(t), x(t - \sigma_1), \ldots, x(t - \sigma_n)). \]
Example Revisited

The DDEs associated with the transcription/translation example are:

\[
\frac{dm(t)}{dt} = \frac{\alpha_m}{1 + (p(t - \sigma_M)/P_0)^h} - \beta_m m(t)
\]

\[
\frac{dp(t)}{dt} = \alpha_p m(t - \sigma_P) - \beta_p p(t)
\]
Eliminating deterministic delays

It is well-known that if you have a sequence of $k$ exponential delays, each with expected duration $\sigma/k$, then as $k \to \infty$ then the end-to-end delay tends to a deterministic delay of duration $\sigma$. 
It is well-known that if you have a sequence of $k$ exponential delays, each with expected duration $\sigma/k$, then as $k \to \infty$ then the end-to-end delay tends to a deterministic delay of duration $\sigma$.

In terms of our models, this means that we can approximate each deterministic delay by a sequence of exponential delays:
Eliminating deterministic delays

It is well-known that if you have a sequence of $k$ exponential delays, each with expected duration $\sigma/k$, then as $k \to \infty$ then the end-to-end delay tends to a deterministic delay of duration $\sigma$.

In terms of our models, this means that we can approximate each deterministic delay by a sequence of exponential delays:

$$n \rightarrow n + u' \rightarrow n + u' + u''$$
Eliminating deterministic delays

It is well-known that if you have a sequence of $k$ exponential delays, each with expected duration $\sigma/k$, then as $k \to \infty$ then the end-to-end delay tends to a deterministic delay of duration $\sigma$.

In terms of our models, this means that we can approximate each deterministic delay by a sequence of exponential delays:

$n \xrightarrow{} n + u' \xrightarrow{} \cdots \xrightarrow{} n + u' + u''$
Replacing the deterministic delay by a sequence of exponential delays means that the underlying stochastic process is again a **CTMC** rather than a **delayed CTMC**.
Eliminating deterministic delays

Replacing the deterministic delay by a sequence of exponential delays means that the underlying stochastic process is again a CTMC rather than a delayed CTMC.

That means that we can once again apply Kurtz’s Theorem knowing that we have convergence to a set of ODEs.
Eliminating deterministic delays

Replacing the deterministic delay by a sequence of exponential delays means that the underlying stochastic process is again a CTMC rather than a delayed CTMC.

That means that we can once again apply Kurtz’s Theorem knowing that we have convergence to a set of ODEs.

Unfortunately this does not immediately tell us anything about the relationship with the set of DDEs generated from the delay population model.
Erlang Approximation
Erlang Approximation
Erlang Approximation

Fluid approximation of CTMC with deterministic delays
Erlang Approximation

This expanded CTMC has more states as we now need to keep track of the phase of the delays as well as the original variables. We are able to prove that, as $N$ tends to infinity, the behaviour of the delayed CTMC and the expanded CTMC are the same.
Erlang Approximation

This expanded CTMC has more states as we now need to keep track of the phase of the delays as well as the original variables.
We are able to prove that, as $N$ tends to infinity, the behaviour of the delayed CTMC and the expanded CTMC are the same.
Convergence in the Example

As $k$ increases the expanded CTMC has better agreement with the delayed CTMC.

Jane Hillston.
Fluid approximation of CTMC with deterministic delays
Erlang Approximation for DDE

We can make the same "Erlang approximation" with the deterministic delays in the DDEs.
Erlang Approximation for DDE

We can make the same “Erlang approximation” with the deterministic delays in the DDEs.

Recall a DDE has the form

$$\frac{dx(t)}{dt} = F(t, x(t), x(t - \sigma_1), \ldots, x(t - \sigma_n)).$$
Erlang Approximation for DDE

We can make the same “Erlang approximation” with the deterministic delays in the DDEs.

Recall a DDE has the form

$$\frac{dx(t)}{dt} = F(t, x(t), x(t - \sigma_1), \ldots, x(t - \sigma_n)).$$

We can approximate each of the $\sigma_i$ by a sequence of small steps.
Erlang Approximation for DDE

Consider the DDE: \( \frac{dx(t)}{dt} = f(x(t - \sigma)) \).
Erlang Approximation for DDE

Consider the DDE: \( \frac{dx(t)}{dt} = f(x(t - \sigma)) \).

We introduce \( k \) variables \( z_1, \ldots, z_k \), representing \( k \) intermediate steps, with

\[
  z_1(t + \sigma/k) = f(x(t))
\]

and

\[
  z_{j+1}(t + \sigma/k) = z_j(t), \quad j = 1, \ldots, k - 1.
\]
Erlang Approximation for DDE

Noting \( \frac{dz_{j+1}(t)}{dt} = \frac{k}{\sigma} (z_j(t) - z_{j+1}(t)) \) we obtain the following set of ODEs:

\[
\begin{align*}
\frac{dz_1(t)}{dt} &= \frac{k}{\sigma} (f(x(t)) - z_1(t)) \\
\vdots \\
\frac{dz_{j+1}(t)}{dt} &= \frac{k}{\sigma} (z_j(t) - z_{j+1}(t)) \\
\vdots \\
\frac{dx(t)}{dt} &= Z_k(t)
\end{align*}
\]
Erlang Approximation for DDE

Noting \( \frac{dz_{j+1}(t)}{dt} = \frac{k}{\sigma} (z_j(t) - z_{j+1}(t)) \) we obtain the following set of ODEs:

\[
\begin{align*}
\frac{dz_1(t)}{dt} &= \frac{k}{\sigma} (f(x(t)) - z_1(t)) \\
\vdots \\
\frac{dz_{j+1}(t)}{dt} &= \frac{k}{\sigma} (z_j(t) - z_{j+1}(t)) \\
\vdots \\
\frac{dx(t)}{dt} &= z_k(t)
\end{align*}
\]

We can show that as \( k \to \infty \) the DDEs and the ODEs exhibit the same behaviour.
DDE Convergence in the Example

Increasing $k$ improves agreement between the ODE and the DDE.

Initial Conditions

Recall that the initial conditions of a DDE are a function in the time interval $[t_0 - \sigma_M, t_0]$, where $\sigma_M$ is the largest delay.
Initial Conditions

Recall that the initial conditions of a DDE are a function in the time interval \([t_0 - \sigma_M, t_0]\), where \(\sigma_M\) is the largest delay.
Initial Conditions

Recall that the initial conditions of a DDE are a function in the time interval $[t_0 - \sigma_M, t_0]$, where $\sigma_M$ is the largest delay.

In contrast, in the CTMC approximation of the delayed CTMC the newly added variables are set to zero, and the effects of delays take place in the future with no effect from the past.
Initial Conditions

Recall that the initial conditions of a DDE are a function in the time interval \([t_0 - \sigma_M, t_0]\), where \(\sigma_M\) is the largest delay.

In contrast, in the CTMC approximation of the delayed CTMC the newly added variables are set to zero, and the effects of delays take place in the future with no effect from the past.
Initial Conditions

Therefore, we consider the solution of the DDE starting not from time $t_0$, but from time $t_0 + \sigma_M$, and construct the initial condition for the DDE from the behaviour of the delayed CTMC in $[t_0, t_0 + \sigma_M]$. 
Conclusions

- We have defined a class of population models in which some events may have delayed effects.
Conclusions

- We have defined a class of population models in which some events may have delayed effects.
- We have shown that the continuous semantics, given in terms of DDEs, and the discrete semantics, given in terms of a delayed CTMC, converge as populations grow.
