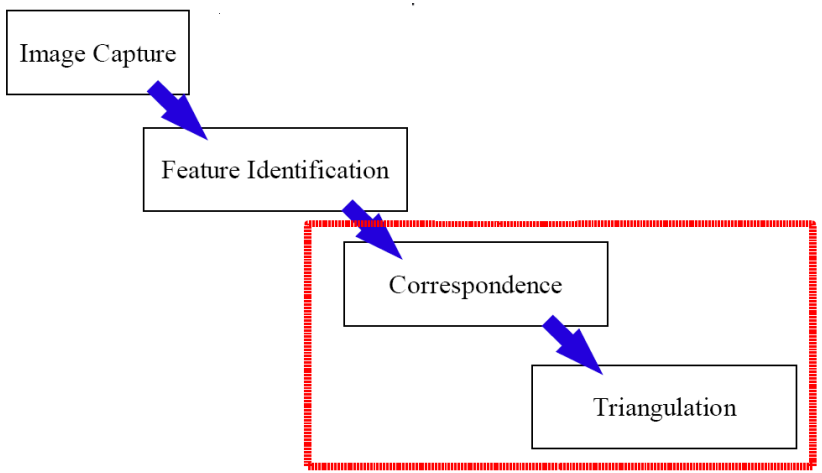
Stereo Correspondence Constraints

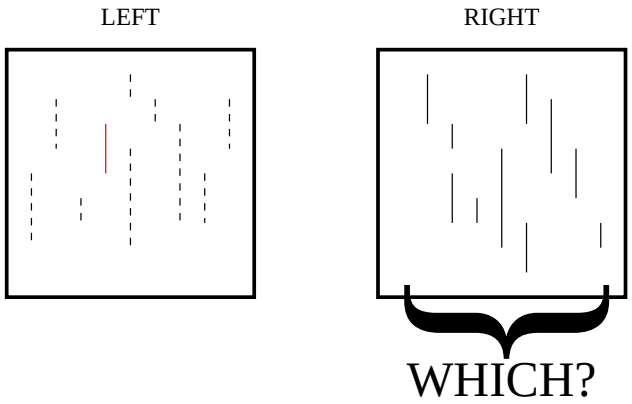
Robert B. Fisher
School of Informatics
University of Edinburgh

Stereo ? Overview



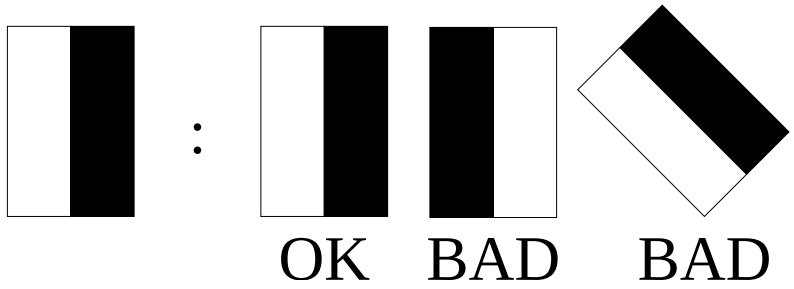
Stereo ? Problem

Which feature in left image matches a given feature in the right?



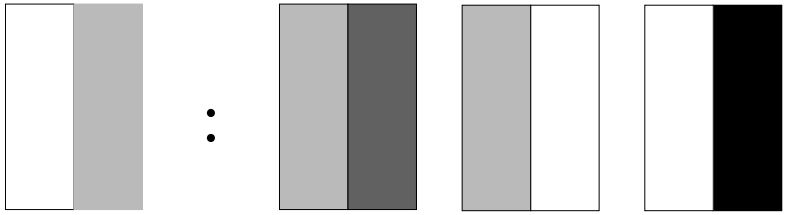
Different pairings give different depth results
Often considered the key problem of stereo

Constraining Matches: Edge Direction



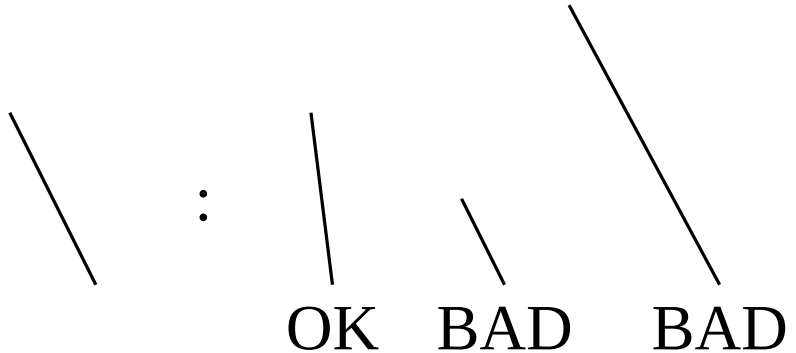
Match features with nearly same ?

Constraining Matches: Edge Contrast



Match features with nearly same [?] across edge

Constraining Matches: Feature Shape



Match features with nearly same [?]

Constraining Matches: Uniqueness and Smoothness

[?]: match features giving nearly same depth as neighbors

Uniqueness: a feature in one image can match from the other image:

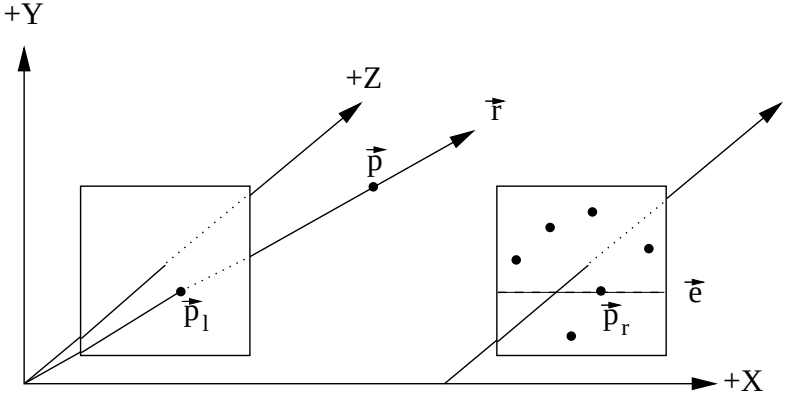
0 - occlusion

1 - normal case

2+ - transparencies, wires, vines, etc from coincidental alignments

Constraining Matches: Epipolar Geometry

Feature $\vec{p}_l$ in left image lies on a [?] $\vec{r}$ thru space.
$\vec{r}$ projects to an epipolar line $\vec{e}$ in the right image, along which the matching image feature must lie.

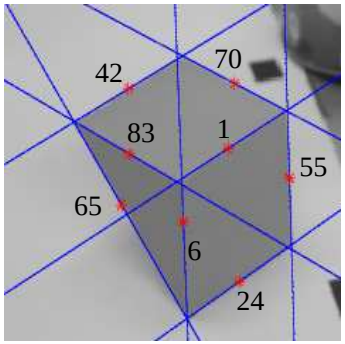


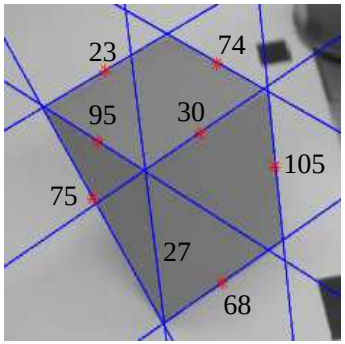
Images are linked by the **Fundamental matrix F**
Epipolar line is defined by: $\vec{e} = F\vec{p}_l$
Matched points satisfy $\vec{p}'_r\vec{e} = 0$

Reduces 2D search to [?

If images are 'rectified', then the epipolar line is an image row

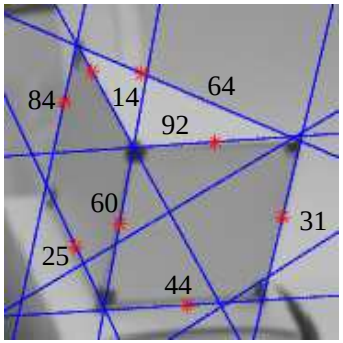
Constrained Matches Block 1

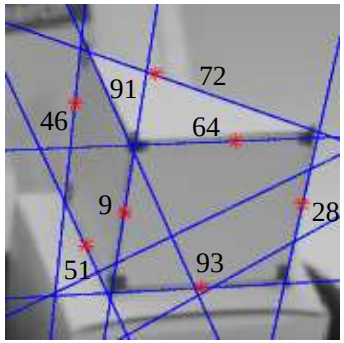




Based on [?], Contrast, Disparity Limit, Epipolar constraints

Constrained Matches Block 2





Lines 92 & 64 did not match ([?] difference related to line positions)

What We Have [?]

- A set of correspondence constraints
- The epipolar constraint
