Bio-PEPA: motivations

Integrated Analysis from
Abstract Stochastic
Process Algebra Models

Jane Hillston.
University of Edinburgh.

Work on the stochastic π -calculus and related calculi, is typically based on Regev's mapping, meaning that a **molecule** maps to a **process**.

This is an inherently **individuals-based** view of the system and analysis will generally then be via stochastic simulation.

Bio-PEPA: motivations

Work on the stochastic π -calculus and related calculi, is typically based on Regev's mapping, meaning that a **molecule** maps to a **process**.

This is an inherently **individuals-based** view of the system and analysis will generally then be via stochastic simulation.

With PEPA and Bio-PEPA we have been experimenting with more **abstract mappings** between elements of signalling pathways and process algebra constructs.

Abstract models are more amenable to **integrative analysis**.

We also wanted to be able to capture more of the **biological features** expressed in the models such as those found in the BioModels database.

Motivations for Abstraction

Integrated Analysis from
Abstract Stochastic
Process Algebra Models

Jane Hillston.
University of Edinburgh.

Our motivations for seeking more abstraction in process algebra models for systems biology are:

Introduction

Bio-PEPA

Stochastic Process Algebra
Reagent-centric modelling
Syntax and semantics

Model Analysis

Mappings to analysis tools
Multiple analyses

Example

Goldbeter's model

Closing remarks

On-going work
Conclusions

Our motivations for seeking more abstraction in process algebra models for systems biology are:

- ▶ Process algebra-based analyses such as **comparing models** (e.g. for equivalence or simulation) and **model checking** are only possible if the state space is not prohibitively large.

Introduction

Bio-PEPA

Stochastic Process Algebra
Reagent-centric modelling
Syntax and semantics

Model Analysis

Mappings to analysis tools
Multiple analyses

Example

Goldbeter's model

Closing remarks

On-going work
Conclusions

Our motivations for seeking more abstraction in process algebra models for systems biology are:

- ▶ Process algebra-based analyses such as **comparing models** (e.g. for equivalence or simulation) and **model checking** are only possible if the state space is not prohibitively large.
- ▶ The data that we have available to parameterise models is sometimes **speculative** rather than precise.

Introduction

Bio-PEPA

Example

Goldbeter's model

Closing remarks

On-going work
Conclusions

Our motivations for seeking more abstraction in process algebra models for systems biology are:

- ▶ Process algebra-based analyses such as **comparing models** (e.g. for equivalence or simulation) and **model checking** are only possible if the state space is not prohibitively large.
- ▶ The data that we have available to parameterise models is sometimes **speculative** rather than precise.

This suggests that it can be useful to use **semi-quantitative** models rather than **quantitative** ones.

On-going work

Conclusions

Consider a conversion of a substrate S , with stoichiometry 2, to a product P , under the influence of an enzyme E , i.e.

In the stochastic π -calculus (for example) this must be modelled as a sequence of unary and binary reactions:

- ▶ $S + S \longrightarrow 2S$
- ▶ $2S + E \longrightarrow 2S:E$
- ▶ $2S:E \longrightarrow P:E$
- ▶ $P:E \longrightarrow P + E$

Conclusions

A Bio-PEPA system \mathcal{P} is a 6-tuple
 $\langle \mathcal{V}, \mathcal{N}, \mathcal{K}, \mathcal{F}_R, \text{Comp}, P \rangle$, where:

- ▶ \mathcal{V} is the set of compartments;
- ▶ \mathcal{N} is the set of quantities describing each species (step size, number of levels, location, ...);
- ▶ \mathcal{K} is the set of parameter definitions;
- ▶ \mathcal{F}_R is the set of functional rate definitions;
- ▶ Comp is the set of definitions of sequential components;
- ▶ P is the model component describing the system.

Conclusions

The system of ODEs is obtained as $\frac{d\bar{x}}{dt} = D \times w$, where $\bar{x}^T = (x_C, x_{M'}, x_M, x_{X'}, x_X)$ is the vector of the species variables:

$$\begin{aligned}\frac{dx_C}{dt} &= v_i \times 1 - k_d \times x_C - \frac{v_d \times x_C \times x_X}{(K_d + x_C)} \\ \frac{dx_{M'}}{dt} &= -\frac{V_{M1} \times x_C}{K_c + x_C} \frac{x_{M'}}{(K_1 + x_{M'})} + \frac{V_2 \times x_M}{(K_2 + x_M)} \\ \frac{dx_M}{dt} &= +\frac{V_{M1} \times x_C}{K_c + x_C} \frac{x_{M'}}{(K_1 + x_{M'})} - \frac{V_2 \times x_M}{(K_2 + x_M)} \\ \frac{dx_{X'}}{dt} &= -\frac{V_{M3} \times x_M \times x_{X'}}{(K_3 + x_{X'})} + \frac{V_4 \times x_X}{(K_4 + x_X)} \\ \frac{dx_X}{dt} &= \frac{V_{M3} \times x_M \times x_{X'}}{(K_3 + x_{X'})} - \frac{V_4 \times x_X}{(K_4 + x_X)}\end{aligned}$$

Conclusions

In a recent extension we consider **events** to be constructs that change the state of the system due to some trigger conditions.

There are several motivations for introducing discrete events into Bio-PEPA. For example,

- ▶ When modelling *in vitro* systems it can be the case that the system is deliberately perturbed in a controlled way at a specific time.
- ▶ There may be discrete changes in systems, such as gene activation and deactivation.

Such an extension of Bio-PEPA has been defined consisting of a separate specification of the events and their effects, and mappings to hybrid automata and stochastic simulation models.

Conclusions

In the current version of Bio-PEPA compartments are simply containers for species, only the size of the compartment being used to calculate concentrations when necessary.

Recent work by Ciocchetta and Guerriero has extended this view of compartments, allowing the relative positioning of compartments and membranes to be captured.

Additionally species and reactions may be specified to have a particular location relative to this structure, for example [on a membrane](#) or [within a compartment](#).

Conclusions

Standard process algebra equivalences, based on the notion of bisimulation have been defined and shown to be congruences [CH TCS08]

Unfortunately these turn out to be very strong notions of equivalence essentially amounting to isomorphism of the biological systems.

We are now seeking to define equivalence and simulation relations for Bio-PEPA which might be more useful from the biological perspective.

In particular we are investigating the situations in which biologists regard models or elements of models to be equivalent, especially when this is employed for model simplification.

Conclusions

Bio-PEPA is a modification of the process algebra PEPA for the *modelling* and *analysis* of biochemical networks.

Bio-PEPA allows us to represent explicitly features of biological networks, such as **stoichiometry** and **general kinetic laws**.

Moreover the **reagent-centric**, abstract style of modelling supports an integrative approach in which several different approaches to analysis may be applied to the same model.

Conclusions (2)

Abstract modelling offers a compromise between the individual-based and population-based views of systems which biologists commonly take.

Moreover we can undertake additional analysis based on the discretised population view.

The abstract Markovian models allow quantities of interest such as “response times” to be expressed as probability distributions rather than single estimates. This may allow better reflection of wet lab data which also shows variability.
